The N-myc oncogene is an early and critical determinant of normal and malignant cell proliferation in vertebrates. Its expression is tightly regulated; consequently, its dysregulation is likely to be an integral component of the abnormal growth and differentiation of cancer cells. N-myc is an essential regulator of transcription and has a primary role in coordinating the complex early steps of differentiation of neurogenic and lymphoid stem cells. N-myc interacts with multiple components of the cell cycle machinery, including essential cyclins, cyclin-dependent kinases, and p53. These interactions appear to modulate the action of N-myc and permit the p53 tumor suppressor to restrict the inappropriate cell growth that can follow N-myc overexpression. In some cases, these interactions appear to enhance the mitogenic activity of N-myc. This review discusses the association of the N-myc protein with the cell cycle, the putative roles of the N-myc protein, and the strategies that might be used to exploit these associations for the development of strategies to combat cancer.

In the book they wrote that the following expression will overflow: $C_1=2*((1\ 6d1f23a050$
